Corrections to the Transmission-Line Parameters of a Coaxial Line When the Center Conductor has Impedance
R. W. Latham

Northrop Corporate Laboratories Pasadena, California

#### Abstract

Transmission-line equations for a uniform coaxial structure whose center conductor has impedance are derived rigorously. These equations reduce to the usual transmission-line equations for coax when the impedance of the center conductor becomes small. In the more general case, the effect of the impedance of the center conductor is to modify the $L$ and the $C$ of the usual transmissionline equations.

The center conductor impedance of an equivalent uniform line is calculated approximately for the case where the center conductor is a row of conducting disks separated by homogeneous dielectric. An outline of a more exact analysis of the disk line is also given.

## I. Introduction

It is of interest, at this time, to measure the impedance per unit length of a structure that, to a first approximation, can be considered a unfform circular cylinder.

One technique for making such a measurement has been suggested by Carl Baum. He proposes to enclose a length of the test cylinder within a hollow circular cylindrical tube, and to measure the transmission-1ine characteristics (say $B(\omega)$, the propagation constant, and $Z(\omega)$, the transmission-1ine impedance) of the cylinder-tube structure. If we also measure the transmission-line characteristics of the structure made up of the same outer tube and a dummy test cylinder, resembling the cylinder under study but having zero impedance per unit length, and, furthermore, assume elementary transmission-line theory to be strictly applicable, we have more than enough information to determine the impedance per unit length of the test cylinder.

Alternatively, it may be possible to calculate, in some simple manner, the inductance or capacitance per unit length of the test cylinder-tube configuration. For example, if the test cylinder can really be accurately approximated by a uniform circular cylinder, the inductance or capacitance calculation is elementary. When such calculations are possible, the measurements with a dummy test cylinder would be unnecessary. There would be enough information to determine the impedance per unit length of the real cylinder without any extra measurements. It would still be necessary to assume, of course, that elementary transmissionline theory is strictly applicable.

The primary purpose of this note is to develop some way to estimate the range of validity of the above measurement technique. The main limitation on the validity would seem to be the assumption that elementary transmission-line theory is strictly applicable. Therefore, we will study the full wave solution of a certain idealized cylinder-tube configuration (a circular coaxial system) and determine under what conditions the formulas for the cylinder's impedance per unit length, in terms of easily measured quantities, go over into the simple formulas that are the result of the transmission-line assumption. Because of their immediate practical interest (and because they are simpler), we will concentrate quite a bit of attention on test cylinders whose impedance per unit length is purely reactive.

One infortant kind of test cylincer can be modelled as a row of closely spaced paraliel disks, separэted by homogeneous dielectric material. A secondary purpose of the present note is to sketch an analytical treatment of such a structure. In Section IV, we will develop an approximate uniform reactive cylinder, equivalent to the disk line, by using some heuristic arguments. A more exact approach to the analysis of such a line is outlined in Section $V$.

## II. Transmission-Line Solution for a Uniform Line

Consider the transmission structure shown in figure 1. Elementary transmission-1ine considerations lead us to the equations

$$
\begin{gather*}
\frac{d I}{d Z}=i \omega C_{0} V  \tag{2.1}\\
\frac{d V}{d Z}=i \omega L_{0} I-Z_{i}(\omega) I \tag{2.2}
\end{gather*}
$$

where $C_{0}$ and $L_{0}$ are certain constants, depending on the geometry of the transmitting structure but not on $\omega$ or $Z_{i}$, and $Z_{i}(\omega)$ is the impedance per unit lergth of the inner conductor. It follows in an elementary fashion that

$$
\begin{equation*}
\beta^{2}(\omega)=\omega^{2} L_{0} C_{0}+i \omega C_{0} Z_{i}(\omega) \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
Z^{2}(\omega)=\frac{i \omega L_{0}-Z_{i}(\omega)}{i \omega C_{0}} \tag{2.4}
\end{equation*}
$$

Elementary transmission-line theory also leads us to state that

$$
\begin{equation*}
L_{0} C_{0}=\mu_{0} \varepsilon_{0} . \tag{2.5}
\end{equation*}
$$

Thus, by defining $\beta_{0}(\omega)$ as the value of $\beta(\omega)$ when $Z_{i}$ is zero, i.e.,

$$
\begin{equation*}
\beta_{0}^{2}(\omega) \equiv \omega^{2} \mu_{0} \varepsilon_{0}, \tag{2.6}
\end{equation*}
$$

we can rewrite equation (2.3) as

$$
\begin{equation*}
\beta^{2}(\omega)=\beta_{0}^{2}(\omega)+i \omega C_{0} Z_{i}(\omega) \tag{2.7}
\end{equation*}
$$

If $Z_{i}(\omega)$ were zero, $Z$ would be equal to $\left(L_{0} / C_{0}\right)^{\frac{1}{2}}$, which we will write as $Z_{0}$. With this notation, equation (2.4) becomes

$z_{i}=$ impedance per unit length of conductor 1.
$C_{0}=$ capacitance per unit length between conductors 1 and 2.
$L_{o}=$ inductance per unit length between conductors 1 and 2.

Figure 1. A uniform transmission structure with inner conductor impedance.

$$
\begin{equation*}
z^{2}(\omega)=z_{o}^{2}+i \frac{z_{i}(\omega)}{\omega C_{o}} \tag{2.8}
\end{equation*}
$$

By rearranging equations (2.7) and (2.8) we can arrive at some formulas for $Z_{i}(\omega)$ in terms of quantities measured with $Z_{i}$ present $(\beta(\omega)$ and $Z(\omega))$ and quantities determined primarily by the geometry of the line ( $\beta_{0}(\omega), Z_{0}, C_{0}$ ). Because of equations (2.5) and (2.6), just one number (together with the value of $\omega$ ) is sufficient to determine all quantities of the second, geometry dependant, type. Some formulas for $Z_{i}$ are

$$
\begin{align*}
z_{i}(\omega) & =i \frac{\beta_{0}^{2}(\omega)-\beta^{2}(\omega)}{\omega C_{o}}  \tag{2.9}\\
& =i \omega C_{0}\left\{z_{o}^{2}-z^{2}(\omega)\right\}  \tag{2.10}\\
& =i\left\{\left[z_{0}^{2}-z^{2}(\omega)\right]\left[\beta_{0}^{2}(\omega)-\beta^{2}(\omega)\right]\right\}^{\frac{1}{2}} \tag{2.11}
\end{align*}
$$

The technique for measuring $Z_{i}(\omega)$ mentioned in the introduction would involve the use of one of the above formulas. In the next section we will see how these formulas are altered, for the special case of circular coax, when a full wave treatment of the problem is considered, rather than the elementary transmission-line treatment we have considered in this section.
III. Wave Solution for a Uniform Line

Consider the special transmission structure that is defined by the inner conductor being a circular cylinder of radius "a" and the outer conductor being a circular cylinder of radius " $b$ ". We will consider the propagation of the lowest TM mode. This mode goes over into the usual TEM mode as the impedance of the inner conductor approaches zero, and this mode will be the only propagating mode at the frequencies of interest. It is an axially symmetric mode, and, employing the usual notation for cylindrical coordinates ([1], p. 51), the only field components present will be $E_{\rho}(\rho, z), E_{z}(\rho, z)$, and $H_{\phi}(\rho, z)$. Two relevant components of Maxwell's equations may be written

$$
\begin{gather*}
\frac{\partial H_{\phi}(\rho, z)}{\partial z}=i \omega \varepsilon_{0} E_{\rho}(\rho, z)  \tag{3.1}\\
\frac{\partial E_{\rho}(\rho, z)}{\partial z}-\frac{\partial E_{z}(\rho, z)}{\partial \rho}=i \omega \mu_{o} H_{\phi}(\rho, z) . \tag{3.2}
\end{gather*}
$$

Let us integrate these equations with respect to $\rho$ between the limits $a$ and $b$. The result is

$$
\begin{gather*}
\frac{\partial}{\partial z} \int_{a}^{b} H_{\phi}(\rho, z) d \rho=i \omega \varepsilon_{o} \int_{a}^{b} E_{\rho}(\rho, z) d \rho  \tag{3.3}\\
\frac{\partial}{\partial z} \int_{a}^{b} E_{\rho}(\rho, z) d \rho=i \omega \mu \int_{a}^{b} H_{\phi}(\rho, z) d \rho+\left.E_{z}(\rho, z)\right|_{a} ^{b} \tag{3.4}
\end{gather*}
$$

Let us make the identifications

$$
\begin{align*}
V(z) & \equiv \int_{a}^{b} E_{\rho}(\rho, z) d \rho  \tag{3.5}\\
I(z) & \equiv 2 \pi a H_{\phi}(a, z)  \tag{3.6}\\
E_{z}^{-}(a, z) & =Z_{i} I(z) \tag{3.7}
\end{align*}
$$

Then, recalling that $E_{z}(b, z)$ is zero, equations (3.3) and (3.4) may be written as

$$
\begin{gather*}
\frac{\partial I(z)}{\partial z}=i \omega C_{0} F V(z)  \tag{3.8}\\
\frac{\partial V(z)}{\partial z}=\frac{i \omega L_{O}}{F} I(z)-Z_{i} I(z) \tag{3.9}
\end{gather*}
$$

where

$$
\begin{align*}
& C_{0}=\frac{2 \pi}{\varepsilon_{0}} \ln (b / a)  \tag{3.10}\\
& L_{0}=\frac{\mu_{0}}{2 \pi} \ln (b / a) \tag{3.11}
\end{align*}
$$

are the usual coaxial transmission-1ine inductance and capacitance per unit length, while

$$
\begin{equation*}
F=a \ln (b / a) \frac{H_{\phi}(a, z)}{\int_{a}^{b} H_{\phi}(\rho, z) d \rho} \tag{3.12}
\end{equation*}
$$

Since, for a single mode, $H_{\phi}(p, z)$ has the same $z$-dependance as $H_{\phi}(a, z)$, $F$ is independant of $z$. Thus, by defining an inductance and capacitance per unit length through

$$
\begin{align*}
& C \equiv C_{0} F  \tag{3.13}\\
& L \equiv L_{0} / F \tag{3.14}
\end{align*}
$$

we can write some transmission-line equations, for the $V$ and $I$ we have defined, in the forms

$$
\begin{equation*}
\frac{\partial I}{\partial z}=\dot{i} \omega C V \tag{3.15}
\end{equation*}
$$

$$
\begin{equation*}
\frac{3 V}{i z}=i n L I-2_{i} I \tag{3.16}
\end{equation*}
$$

By noting that

$$
\begin{align*}
\omega^{2} L C & =\omega^{2} L_{0} C_{0}=\beta_{0}^{2}(\omega)  \tag{3.17}\\
\frac{L}{C} & =\frac{1}{F^{2}} \frac{L_{0}}{C_{0}}=\frac{1}{E^{2}} Z_{o}^{2} \tag{3.18}
\end{align*}
$$

we can use the similarity of form between equations (2.1), (2.2) and (3.15), (3.16) to say, from equations (2.9), (2.10), and (2.11), that

$$
\begin{align*}
Z_{i}(\omega) & =i\left\{\frac{\beta_{0}^{2}(\omega)-\beta^{2}(\omega)}{\omega C_{o}^{F}}\right\}  \tag{3.19}\\
& =i \omega C_{o} F\left\{\frac{Z_{0}^{2}}{F^{2}}-Z^{2}(\omega)\right\}  \tag{3.20}\\
& =i\left\{\left[\frac{Z_{o}^{2}}{F^{2}}-Z^{2}(\omega)\right]\left[\beta_{o}^{2}(\omega)-\beta^{2}(\omega)\right]\right\}^{1 / 2} \tag{3.21}
\end{align*}
$$

It is clear that these equations reduce to the more elementary equations of the previous section if $F$ is equal to unity. This will be true if $Z_{i}$ is very small, since in that case

$$
\begin{equation*}
\mathrm{H}_{\phi}(\rho, z) \simeq(\mathrm{a} / \rho) \mathrm{H}_{\phi}(\mathrm{a}, z) \tag{3.22}
\end{equation*}
$$

and substituting equation (3.22) into equation (3.12) leads quickly to the result that $F$ is unity.

We must now determine how $F$ changes as $Z_{i}$ increases, and thus find out how much we can trust equations (2.9) , (2.10) and (2.11).

For the mode we are interested in, the three field components may be written in the forms

$$
\begin{gather*}
E_{z}(\rho, z)=E_{0}\left\{Y_{0}(\alpha r) J_{0}(\alpha \rho / a)-J_{0}(\alpha r) Y_{0}(\alpha \rho / a)\right\} e^{i \beta_{0} \sqrt{1-\left(\alpha / \beta_{0} a\right)^{2}} z}  \tag{3.23}\\
\frac{H_{\phi}(\rho, z)}{E_{0}}=-\frac{i \omega \varepsilon_{0} a}{\alpha}\left\{Y_{0}(\alpha r) J_{1}(\alpha \rho / a)-J_{0}(\alpha r) Y_{1}(\alpha \rho / a)\right\} e^{i \beta_{0} \sqrt{1-\left(\alpha / \beta_{0} a\right)^{2}} z}  \tag{3.24}\\
E_{\rho}(\rho, z)=-\frac{i a}{\alpha} \sqrt{\beta_{0}^{2}-\alpha / a^{2}} E_{0}\left\{Y_{0}(\alpha r) J_{1}(\alpha \rho / a)-J_{0}(\alpha r) Y_{1}(\alpha \rho / a)\right\} e^{i \beta_{0} \sqrt{1-(\alpha / \beta a)^{2}} z} \tag{3.25}
\end{gather*}
$$

where the usual notation for Bessel functions ([2], Chap. 9) has been used, and we have already satisfied the condition that $E_{z}(b, z)$ be zero. Note that, in writing the above equations, we have used the notation

$$
r \equiv b / a .
$$

The $\alpha$ of equations (3.23), (3.24), and (3.25) must be determined from the impedance condition at the inner cylinder, i.e.,

$$
\begin{equation*}
\frac{1}{Z_{i}}=\frac{2 \pi a H_{\phi}(a, z)}{E_{z}(a, z)}=-\frac{i \omega \varepsilon_{0}\left(2 \pi a^{2}\right)}{\alpha}\left\{\frac{Y_{0}(\alpha r) J_{1}(\alpha)-J_{0}(\alpha r) Y_{1}(\alpha)}{Y_{0}(\alpha r) J_{0}(\alpha)-J_{0}(\alpha r) Y_{0}(\alpha)}\right\} \tag{3.26}
\end{equation*}
$$

In this note we are primarily interested in reactive $Z_{i}$, and so we will write

$$
\begin{equation*}
z_{i}=\frac{S_{r}}{-i \omega \varepsilon_{0} \pi a^{2}} \tag{3.27}
\end{equation*}
$$

where $S_{r}$ is the elastance per unit length of the inner cylinder normalized to the free space elastance per unit length of that cylinder. Note that this elastance notation is mainly a matter of convenience; $S_{r}$ could actually be a function of frequency without disturbing any of the following arguments. Now, from equations (3.26) and (3.27), we can rewrite the $\alpha$ equation in the form

$$
\begin{equation*}
\alpha^{2}=2 S_{r} \alpha\left\{\frac{Y_{0}(\alpha r) J_{1}(\alpha)-J_{0}(\alpha r) Y_{1}(\alpha)}{Y_{0}(\alpha r) J_{0}(\alpha)-J_{0}(\alpha r) Y_{0}(\alpha)}\right\} \tag{3.28}
\end{equation*}
$$

Now let us see what $F$ is. From equations (3.12) and (3.24) it follows that

$$
\begin{equation*}
F=\frac{a \ln r}{(a / \alpha)}\left\{\frac{Y_{0}(\alpha r) J_{1}(\alpha)-J_{0}(\alpha r) Y_{1}(\alpha)}{Y_{0}(\alpha r) J_{0}(\alpha)-J_{0}(\alpha r) Y_{0}(\alpha)}\right\}, \tag{3.29}
\end{equation*}
$$

and thus, making use of equation (3.28),

$$
\begin{equation*}
F=\frac{a^{2} \ln r}{2 S_{r}} \tag{3.30}
\end{equation*}
$$

So we see that for each value of $r$ and $S_{r}$ we must solve equation (3.28) (possibly by an iteration based on the equation resulting from taking the square root of both sides of that equation), and then compute $F$ from equation (3.30). A rather pleasant way to compute the Bessel function cross products in equation (3.28) is given in the appendix, where it is shown that

$$
\begin{equation*}
\alpha\left\{\frac{Y_{0}(\alpha r) J_{1}(\alpha)-J_{0}(\alpha r) Y_{1}(\alpha)}{Y_{0}(\alpha r) J_{0}(\alpha)-J_{0}(\alpha r) Y_{0}(\alpha)}\right\}=\frac{2}{r^{2}-1} \frac{\sum_{k=1}^{\infty} T_{k}}{\sum_{k=1}^{\infty}\left(T_{k} / k\right)} \tag{3.31}
\end{equation*}
$$

where

$$
\begin{align*}
& T_{1}=1  \tag{3.32}\\
& T_{2}=\frac{r^{2}-1}{r^{2}} \tag{3.33}
\end{align*}
$$

and

$$
\begin{equation*}
T_{k+1}=\frac{r^{2}-1}{r^{2}}\left\{T_{k}-\frac{\alpha^{2}\left(r^{2}-1\right)}{4} \cdot \frac{T_{k-1}}{k(k-1)}\right\} \tag{3.34}
\end{equation*}
$$

From the appendix it also follows that, as $\alpha$ approaches zero, the right hand side of equation (3.31) approaches ( $1 / \ln _{\mathrm{n}} r$ ). Thus, for small $\mathrm{S}_{\mathrm{r}}$ (which corresponds to small $\alpha$ ), equation (3.28) gives $\alpha^{2}=\left(2 S_{r} / \ln r\right)$, and thus equation (3.30) leads to $F=1$, as we would hope. The values of $F$ for several other values of $S_{r}$ and $r$ are given in table 1 , along with the corresponding values of $\alpha$ and $\alpha^{2}$. This data is also presented graphically in figures 2, 3 ,

4, and 5.
In Table 2 and figure 6 we give some data on ( $\alpha \mathrm{b} / \mathrm{a}$ ) vs. ( $\mathrm{a} / \mathrm{b}$ ) for a few values of $S_{r}$. This information is presented as a matter of interest. If there were no center conductor, ( $\alpha b / a$ ) would be the first root of $J_{0}(x)$, i.e., 2.4048. We approach this value more rapidly, as ( $a / b$ ) approaches zero, if $S_{r}$ is large.

Table 1 enables us to tell if the $S_{r}$ we calculate from some measurements, by the technique described in the introduction, is low enough for the technique to be accurate (i.e., low enough for $F$ to be close to unity). Another way to look at this data is given in figure 7 , where the maximum $S_{r}$ that keeps $F$ greater than . 99 , . 95 and . 9 is plotted vs. ( $\mathrm{a} / \mathrm{b}$ ).

We note from equations (2.9) and (3.19) that what we actually compute, when we use equation (2.9), is not $Z_{i}(\omega)$ but $F Z_{i}(\omega)$. But $F$ is itself a function of $Z_{i}$ (and $r$ ). We may recover $Z_{i}$ from $F Z_{i}$ by using the data of table 1 . The result is a corrected version of equation (2.9) which, for the case where $Z_{i}$ is equal to $i\left(S_{r} / \omega \varepsilon_{0} \pi a^{2}\right)$, we have displayed graphically as figure 8. By usirig figure 8, a measurement of the propagation constant of the line is enough to give us an accurate value of $S_{r}$, without the approximation involved in assuming elementary transmission-line theory to be strictly applicable.

Before closing this section, it might be well to say again explicitly why we have gone to the trouble of tabulating $F$ in various ways. The reason is that, for the coaxial line, $1-F$ is a measure of the crror incurred by using, equations such as (2.9), (2.10), and (2.11) rather than the accurate relations (3.19), (3.20), and (3.21). Thus $1-F$ should also be a measure of the error due to using elementary transmission-line formulas when the measurement setur is almost, but not exactly, coaxial. The fact that $1-F$ is a measure of the error for the coaxial case is clear, and rigorous, when one uses equation (2.9) instead of Equation (3.19) for, denoting the approximate $Z_{i}$ by $\bar{Z}_{i}$, we have, from equations (2.9) and (3.19),

$$
\frac{z_{i}-\bar{z}_{i}}{z_{i}}=1-F
$$

But, even if one of the other formulas for $z_{i}$ were used, $1-F$ can still be used to get a first order estimate of the relative error in $Z_{i}$ in the coaxial.

Figure 8. A corrected version of equation (2.9).
case. For example, if equation (2.11) were used instead of equation (3.21), we have

$$
\frac{z_{i}-\bar{z}_{i}}{z_{i}}=I-F\left\{\frac{z_{0}^{2}-z^{2}}{z_{0}^{2}-F^{2} z^{2}}\right\}^{1 / 2}
$$

or, if $1-F \equiv \delta$,

$$
\begin{aligned}
\frac{z_{i}-\overline{z_{i}}}{z_{i}} & =1-F\left\{\frac{z_{0}^{2}-z^{2}}{z_{0}^{2}-z^{2}+2 \delta z^{2}-\delta^{2} z^{2}}\right\}^{\frac{1}{2}} \\
& =\delta \cdot \frac{1}{1-\left(z / z_{0}\right)^{2}}+0\left(\delta^{2}\right)
\end{aligned}
$$

A11 relevant quantities in the final expression are easily obtainable from measurements or the tables, and so we can quickly determine if equation (2.11) is adequate in any given case.
IV. Uniform Line Equivalent of a Disk Line

Consider the transmitting structure shown in figure 9. The center "conductor" of this structure is made up of a row of uniformly spaced metalilic disks, separated by a homogeneous dielectric. This structure is an idealized model of a structure that is of practical importance. Let us see what can be done toward an analytical treatment of this structure. In this section, we will briefly derive an approximate $z_{i}$ for the row of disks, based on some rather handwaving arguments, and present some numerical data on this approximate $Z_{i}$. In the next section, we will outline a more exact approach.

If the disks of figure 9 are close together, compared to their radii, then between each pair of disks the dominant electric field will be along the $z$-axis, and will vary very little with $z$. Thus, approximate equations for the fields between the disks are

$$
\begin{align*}
& E_{z}(\rho, z) \simeq E_{0} J_{0}\left(n \beta_{0} \rho\right)  \tag{4.1}\\
& \frac{H_{\phi}(\rho, z)}{E_{0}} \simeq \frac{-i}{Z_{1}} J_{1}\left(n \beta_{0} \rho\right) \tag{4.2}
\end{align*}
$$

where

$$
\begin{align*}
& z_{1} \equiv \frac{1}{n} \sqrt{\frac{\mu_{0}}{\varepsilon_{0}}}  \tag{4.3}\\
& \eta^{2} \equiv \varepsilon / \varepsilon_{0} \tag{4.4}
\end{align*}
$$

$$
\beta_{o}^{2} \equiv \omega^{2} \mu_{0} \varepsilon_{0}
$$

If equations (4.1) and (4.2) were good approximations all the way out to $\rho=a$ (and these approximations improve as $\Delta / a$ decreases) then, from the definition of $z_{i}$, we could say immediately that

$$
\begin{equation*}
Z_{i}=\frac{J_{0}\left(n \beta_{0} a\right)(\delta / \Delta)}{2 \pi a\left(-i / Z_{1}\right) J_{1}\left(n \beta_{0} a\right)} \tag{4.6}
\end{equation*}
$$

Figure '9. A disk line.
where the $E_{z}$ field at $\rho=a$, which is nonzero only between the disks, has been averaged over a full $\Delta$ period of the structure.

In order to make use of the tables of the previous section, it would be more useful to write an equivalent $S_{r}$ from the above $Z_{i}$. It is not hard to see that this equivalent $S_{r}$ is just

$$
\begin{align*}
S_{r}=Z_{i}\left(-i \omega \varepsilon_{0} \pi a^{2}\right) & =\omega \varepsilon_{0} a Z_{1} \frac{J_{0}\left(n \beta_{o} a\right)}{2 J_{1}\left(n \beta_{o} a\right)}(\delta / \Delta)  \tag{4.7}\\
& =\frac{(\delta / \Delta)}{n^{2}} g\left(n \beta_{o} a\right) \tag{4.8}
\end{align*}
$$

where

$$
\begin{equation*}
g(x)=\frac{x J_{0}(x)}{2 J_{1}(x)} \tag{4.9}
\end{equation*}
$$

We have tabulated $g(x)$ in table 3 and drawn it in figure 10 . From this data, and the tables of the previous section, one can determine the approximate behavior of a disk line.

Table 3. Auxiliary function for computing the effective $S_{r}$ of a disk line.

Figure 10. Auxiliary function for computing effective $S_{r}$ of a disk line.

## V. A: Fxact Approa . 1 or a Disk line

Since the line whose iciealized model is given as figure 9 is of more than passing practical interest, it may be helpíll to have available a more exact analysis of such a structure than can be obtained by assuming an "equivalent" uniform line, as we did in the previous section.

A structure quite similar to that of figure 9 , the iris-loaded circular waveguide, has received quite a bit of attention in the literature because of its use in linear accelerators. All we need to do here is to make some slight changes in the available analyses of iris-loaded structures. The result will be an fnfinite determinantal equation (to be truncated and evaluated numerically) for the determination of the propagation constants of the various modes that can exist in the disk line.

We will follow closely the analysis of the iris-loaded line by Walkinshaw [3] (a previous, better known, paper by Walkinshaw gave an approximate analysis of the iris-loaded guide; reference [3] gives a shorter, more accurate analysis). For the sake of simplicity, we will treat only the case of infinitesimally thin disks ( $\delta=\Delta$ ).

In the outer ( $a<\rho<b$ ) region of the disk Iine, we will write the fields in the form

$$
\begin{gather*}
E_{z}^{I I}(\rho, z)=\sum_{m=-\infty}^{\infty} e_{m} \frac{F_{0}\left(\alpha_{m} ; r, \pi / a\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)} e^{i\left(\beta+\frac{2 \pi m}{\Delta}\right) z}  \tag{5.1}\\
H_{\phi}^{I I}(\rho, z)=-i \omega \varepsilon_{0} a \sum_{m=-\infty}^{\infty} \frac{e_{m}}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, \rho / a\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)} e^{i\left(\beta+\frac{2 \pi m}{\Delta}\right) z} \tag{5.2}
\end{gather*}
$$

where

$$
\begin{gather*}
r \equiv b / a \\
\left(\frac{\alpha}{a}\right)^{2}=\beta_{o}^{2}-\left(\beta+\frac{2 \pi m}{\Delta}\right)^{2} \tag{5.4}
\end{gather*}
$$

and

$$
\begin{align*}
& F_{0}\left(\alpha_{m} ; r, \rho / a\right) \equiv Y_{0}\left(\alpha_{m} r\right) J_{0}\left(\alpha_{m} \rho / a\right)-J_{0}\left(\alpha_{m} r\right) Y_{0}\left(\alpha_{m} \rho / a\right)  \tag{5.5}\\
& F_{1}\left(\alpha_{m} ; r, \rho / a\right) \equiv Y_{0}\left(\alpha_{m} r\right) J_{1}\left(\alpha_{m} \rho / a\right)-J_{0}\left(\alpha_{m} r\right) Y_{1}\left(\alpha_{m} \rho / a\right) \tag{5.6}
\end{align*}
$$

Equations (5.1) and (5.2) are the forms established by Floquet's theorem and the boundary condition on $E_{z}$ at the surface $\rho=b$.

In the inner ( $\rho<a$ ) region, we will choose a form for the fields that is finite on the $z$-axis and has zero radial field on the disks. Such a form; in the basic region ( $-\Delta / 2<z<\Delta / 2$ ) (note that in the region ( $N-\frac{1}{2}$ ) $\Delta<z<\left(N+\frac{1}{2}\right) \Delta$ ) we must multiply each $B_{s}$ and $D_{s}$ coefficient by $e^{i N B \Delta}$ ) is:

$$
\begin{align*}
& E_{z}^{(I)}(\rho, z)=\sum_{s=0}^{\infty} B_{s} \frac{J_{0}\left(\gamma_{s} \rho / a\right)}{J_{0}\left(\gamma_{s}\right)} \cos \left(\frac{2 \pi s z}{\Delta}\right)+\sum_{s=1}^{\infty} D_{s} \frac{J_{0}\left(\gamma_{s}^{\prime} \rho / a\right)}{J_{0}\left(\gamma_{s}^{\prime}\right)} \sin \left(\frac{2 s-1}{\Delta} \pi z\right)  \tag{5.7}\\
& \frac{H_{\phi}^{(I)}(\rho, z)}{-i \omega \varepsilon}=\sum_{s=0}^{\infty} \frac{B_{s}}{\gamma_{s}} \frac{J_{1}\left(\gamma_{s} \rho / a\right)}{J_{0}\left(\gamma_{s}\right)} \cos \left(\frac{2 \pi s z}{\Delta}\right)+\sum_{s=1}^{\infty} \frac{D_{s}}{\gamma_{s}^{\prime}} \frac{J_{1}\left(\gamma_{s}^{\prime} \rho / a\right)}{J_{0}\left(\gamma_{s}^{\prime}\right)} \sin \left(\frac{2 s-1}{\Delta} \pi z\right) \tag{5.8}
\end{align*}
$$

where

$$
\begin{gather*}
\left(\frac{\gamma_{s}}{a}\right)^{2}=\beta_{0}^{2}-\left(\frac{2 \pi s}{\Delta}\right)^{2}  \tag{5.9}\\
\left(\frac{\gamma_{s}^{\prime}}{a}\right)^{2}=\beta_{0}^{2}-\left(\frac{2 s-1}{\Delta} \pi\right)^{2} \tag{5.10}
\end{gather*}
$$

By matching the two representations for $E_{z}$ on the $\rho=a$ surface, we obtain the relations

$$
\begin{align*}
B_{0} \Delta & =\sum_{m=-\infty}^{\infty} e_{m} C_{o m}  \tag{5.11}\\
\frac{1}{2} B_{s} \Delta & =\sum_{m=-\infty}^{\infty} e_{m} C_{s m} \tag{5,12}
\end{align*}
$$

$$
\begin{equation*}
\frac{1}{2} D_{s} \Delta=\Gamma_{m--\infty}^{\infty} \overbrace{m} S_{s m} \tag{5.13}
\end{equation*}
$$

where

$$
\begin{align*}
C_{s m} & =\int_{-\Delta / 2}^{\Delta / 2} \cos \left(\frac{2 \pi s z}{\Delta}\right) e^{i\left(\beta+\frac{2 \pi m}{\Delta}\right) z} d z \\
& =2(-)^{m+s} \sin \left(\frac{\beta \Delta}{2}\right) \frac{\beta+(2 \pi m / \Delta)}{[\beta+(2 \pi m / \Delta)]^{2}-(2 \pi s / \Delta)^{2}} \tag{5.14}
\end{align*}
$$

and

$$
\begin{align*}
S_{s m} & =\int_{-\Delta / 2}^{\Delta / 2} \sin \left(\frac{2 s-1}{\Delta} \pi z\right) e^{i\left(\beta+\frac{2 \pi m}{\Delta}\right) z} d z \\
& =2 i(-)^{m+s} \cos \left(\frac{\beta \Delta}{2}\right) \frac{\beta+(2 \pi m / \Delta)}{[\beta+(2 \pi m / \Delta)]^{2}-[\pi(2 s-1 / \Delta)]^{2}} \tag{5.15}
\end{align*}
$$

Now we must also match the two representations for $H_{\phi}$ on the $\rho=a$ surface. These matching equations take the form

$$
\begin{align*}
& \frac{B_{0} \Delta}{\gamma_{0}} n^{2} \frac{J_{1}\left(\gamma_{0}\right)}{J_{0}\left(\gamma_{0}\right)}=\sum_{m=-\infty}^{\infty} \frac{e_{m}}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, 1\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)} c_{o m}  \tag{5.16}\\
& \frac{B_{s} \Delta}{2 \gamma_{s}} \eta^{2} \frac{J_{1}\left(\gamma_{s}\right)}{J_{o}\left(\gamma_{s}\right)}=\sum_{m=-\infty}^{\infty} \frac{e_{m}}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, 1\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)} c_{s m}  \tag{5.17}\\
& \frac{D_{s} \Delta}{2 \gamma_{s}^{\prime}} \eta^{2} \frac{J_{1}\left(\gamma_{s}^{\prime}\right)}{J_{0}\left(\gamma_{s}^{\prime}\right)}=\sum_{m=-\infty}^{\infty} \frac{e_{m}}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, 1\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)} s_{s m} \tag{5.18}
\end{align*}
$$

or, making use of equations (5.11), (5.12), and (5.13),

$$
\begin{equation*}
\sum_{m=-\infty}^{\infty} e_{m} c_{s m}\left\{\frac{n^{2}}{\gamma_{s}} \frac{J_{1}\left(\gamma_{s}\right)}{J_{0}\left(\gamma_{s}\right)}-\frac{1}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, 1\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)}\right\}=0 \quad s=0,1, \cdots \infty \tag{5.19}
\end{equation*}
$$

$$
\begin{equation*}
\sum_{m=-\infty}^{\infty} e_{m} s_{s m}\left\{\frac{n^{2}}{\gamma_{s}^{\prime}} \frac{J_{1}\left(\gamma_{s}^{\prime}\right)}{J_{0}\left(\gamma_{s}^{\prime}\right)}-\frac{1}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, 1\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)}\right\}=0 \quad s=1,2, \cdots \infty \tag{5.20}
\end{equation*}
$$

We may give these equations a little more presentable appearance by multiplying the first set by

$$
\frac{(-)^{s}}{2 \Delta \sin (\beta \Delta / 2)}
$$

the second set by

$$
\frac{(-)^{s}}{2 i \Delta \cos (\beta \Delta / 2)}
$$

and defining new variables $e_{m}^{\prime}$ by $e_{m}^{\prime} \equiv(-)^{m} e_{m}$. The truncated version of equations equivalent to (5.19) and (5.20) may then be written in the form

$$
\begin{equation*}
\sum_{m=-N}^{N} M_{s m} e_{m}^{\prime}=0 \quad s=0,1, \cdots 2 N \tag{5.21}
\end{equation*}
$$

where

$$
\begin{equation*}
M_{s m}=\frac{\Delta \beta+2 \pi m}{(\Delta \beta+2 \pi m)^{2}-(\pi s)^{2}}\left\{\frac{\pi^{2}}{\Gamma_{2}} \frac{J_{1}\left(\Gamma_{s}\right)}{J_{0}\left(\Gamma_{s}\right)}-\frac{1}{\alpha_{m}} \frac{F_{1}\left(\alpha_{m} ; r, 1\right)}{F_{0}\left(\alpha_{m} ; r, 1\right)}\right\} \tag{5.22}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\frac{\Gamma_{s}}{a}\right)^{2} \equiv \beta_{0}^{2}-\left(\frac{\pi s}{\Delta}\right)^{2} \tag{5.23}
\end{equation*}
$$

The propagation constant, $\beta$, is determined by setting the determinant of the set (5.21) equal to zero (there are several roots of course; we are interested primarily in the smallest one). The accuracy increases as we increase $N$. If $N$ is zero we return to the approximation of the previous section (for $\delta=\Delta$ ). Walkinshaw effectively says that, in the case of the iris-loaded guide, we get about one part in a thousand error in $B$, if $\Delta / a$ is not too large, when $N$ is one. There should be no great difficulty in obtaining very accurate values of $B$ in the present case, should it become desirable to do so.

The present analysis can be readily extended to the case where the disks have finite thickness. It just gets about twice as messy.

## VI. Conclu=ion

The main result of this note is that, with the tables and curves of Bection III, we have available a way to tell whether the impedance per unit length, measured and calculated by the simpie techniques of Sections $I$ and II, is really the impedance per unit length of the structure under test.

The tables and curves of Section III could be extended, in some future note, to include complex values of $Z_{i}$, rather than the pure fmaginary values of $Z_{i}$ that we have examined here. The same development, including equation (3.28) and equations (3.31) to (3.34), would hold in the more general case ( $S_{r}$ and $\alpha$ would be complex). It is believed that, for the test structures that are presently of interest (which have a dominantly imaginary $Z_{i}$ ) the present data should be sufficient.

A secondary result of the note is the beginning of an accurate analysis of a disk line. Should it become necessary, it would be straightforward to carry out numerical work, based on the present analytical work.

An Algorithm for Two Bessel Function Crossproducts
In this appendix we will develop expressions that are well suited to numerical evaluation for the two Bessel function crossproducts used in the note

$$
\begin{align*}
& B_{0}(\alpha, r)=(\pi / 2)\left[Y_{0}(\alpha r) J_{0}(\alpha) \cdots J_{0}(\alpha r) Y_{0}(\alpha)\right]=(\pi / 2) F_{0}(\alpha ; r, 1)  \tag{A.1}\\
& B_{1}(\alpha, r)=(\alpha \pi / 2)\left[Y_{0}(\alpha r) J_{1}(\alpha)-J_{0}(\alpha r) Y_{1}(\alpha)\right]=(\alpha \pi / 2) F_{1}(\alpha ; r, 1) \tag{A.2}
\end{align*}
$$

From the multiplication theorem for Bessel functions ([2], p. 363), setting ( $\alpha r$ ) $=x$, we get

$$
\begin{equation*}
B_{0}(\alpha, r)=\frac{\pi}{2} \sum_{k=0}^{\infty} \frac{\left(1-1 / r^{2}\right)^{k}(x / 2)^{k}}{k!}\left[Y_{0}(x) J_{k}(x)-J_{0}(x) Y_{k}(x)\right] \tag{A.3}
\end{equation*}
$$

The first term in this series disappears. The crossproducts within the series satisfy the difference equation for Bessel functions; i.e., if

$$
\begin{equation*}
c_{k} \equiv(\pi / 2)\left[Y_{0}(x) J_{k}(x)-J_{0}(x) Y_{k}(x)\right] \tag{A.4}
\end{equation*}
$$

we have

$$
\begin{equation*}
c_{k+1}=\frac{2 k}{x} c_{k}-c_{k-1} \tag{A.5}
\end{equation*}
$$

with

$$
\begin{gather*}
c_{1}=(1 / x)=(1 / \alpha r)  \tag{A.6}\\
c_{2}=\left(2 / x^{2}\right)=\left(2 / \alpha^{2} r^{2}\right) \tag{A.7}
\end{gather*}
$$

and we can write

$$
\begin{equation*}
B_{0}(\alpha, r)=\sum_{k=1}^{\infty}\left(\frac{r-1 / r}{2}\right)^{k} \frac{\alpha^{k}}{k!} c_{k} \tag{k,8}
\end{equation*}
$$

In a similar manner it follows that

$$
\begin{align*}
B_{1}(\alpha, r) & =\frac{\alpha \pi}{2 r} \sum_{k=0}^{\infty} \frac{\left(1-1 / r^{2}\right)^{k}(x / 2)^{k}}{k!}\left[Y_{o}(x) J_{k+1}(x)-J_{0}(x) Y_{k+1}(x)\right]  \tag{A.9}\\
& =\frac{\alpha}{r} \sum_{k=1}^{\infty}\left(\frac{r-1 / r}{2}\right)^{k-1} \frac{\alpha^{k-1}}{(k-1)!} c_{k} \tag{A.10}
\end{align*}
$$

Now let us define some new coefficients through

$$
\begin{equation*}
T_{k}=\alpha r\left(\frac{r-1 / r}{2}\right)^{k-1} \frac{\alpha^{k-1}}{(k-1)!} c_{k} \tag{A.11}
\end{equation*}
$$

thus

$$
\begin{equation*}
\mathrm{B}_{1}(\alpha, \mathrm{r})=\frac{1}{\mathrm{r}^{2}} \sum_{\mathrm{k}=1}^{\infty} \mathrm{T}_{\mathrm{k}} \tag{A.12}
\end{equation*}
$$

and

$$
\begin{equation*}
B_{o}(\alpha, r)=\frac{r^{2}-1}{2 r^{2}} \sum_{k=1}^{\infty} \frac{T_{k}}{k} \tag{A,13}
\end{equation*}
$$

while, from equation (A.11) and the difference equation for $c_{k}$, it follows that

$$
\begin{equation*}
T_{k+1}=\frac{r^{2}-1}{r^{2}}\left\{T_{k}-\frac{\alpha^{2}\left(r^{2}-1\right)}{4} \cdot \frac{T_{k-1}}{k(k-1)}\right\} \tag{A.14}
\end{equation*}
$$

with

$$
\begin{align*}
& \mathrm{T}_{1}=1  \tag{A.15}\\
& \mathrm{~T}_{2}=\frac{r^{2}-1}{\mathrm{r}^{2}} \tag{A.16}
\end{align*}
$$

Expressions (A.12) and (A.13) are easy to evaluate, with even a desktop computer. The $T_{k}$ 's are generated from equation (A.14), using equations (A.15) and (A.16) to get started. Equations (A.12) to (A.16) make up the algorithm we have been aiming at.

Note that, if $\alpha=0, T_{k}=\left(1-1 / r^{2}\right)^{k-1}$, and so

$$
\begin{aligned}
& B_{1}(0, r)=\frac{1}{r^{2}} \sum_{k=1}^{\infty}\left(\frac{r^{2}-1}{r^{2}}\right)^{k-1}=1 \\
& B_{0}(0, r)=\frac{r^{2}-1}{2 r^{2}} \sum_{k=1}^{\infty}\left(\frac{r^{2}-1}{r^{2}}\right)^{k-1} \cdot \frac{1}{k}=\ln r
\end{aligned}
$$
