#### Abstract

Curves of the positions of the points which divide a two-plate transmission line into three, four, five or six sections of equal impedance are presented. Approximations to these curves are deduced for the cases where the two plates are either very far apart or very close together.

## Acknowledgment:

We are grateful to Mr. R. W. Sassman for his valuable assistance in the numerical work, and to Mrs. G. Peralta for her help in preparing the manuscript.

## I. Introduction

A parallel-plate transmission line may be used to simulate the nuclear electromagnetic pulse. The characteristics of such a structure have been described extensively in previous notes in this series. ${ }^{1,3}$ In order to excite the parallel-plate simulator by realistic energy sources, some sort of-transition section is necessary. ${ }^{2}$ This transition section may take the form of a single conical section or several sections in parallel.

A determination of the shape that the multiple-transition sections should take in order to maintain a constant impedance per section as they gradually taper to the sources from the top plate of the simulator has been made. ${ }^{4}$ The calculations were based on the assumption that the transition region is an infinite periodic structure. The fact that there are really only a few transition sections can make edge effects important. In particular the sections, when they meet the upper plate of the simulator, should not all be of equal width if the impedance looking into each is to be the same. The reason for this is that the charge distribution on the upper plate of the simulator is non-uniform.

The general problem of determining the proper shape of the transition sections when there are only a finite number of them present is quite complex. This may have to be done in the future if measurements should show serious impedance mismatches. In this note we merely make a first guess at the solution of the general problem by determining where the various sections should meet the top plate in order that they all have the same impedance. This will be done by dividing the top plate into three, four, five and six sections, each section containing equal charge per unit length. Perhaps the data presented here, in conjunction with the information derived from the calculations for the periodic structure, ${ }^{4}$ will permit an adequate prescription of the shape of the transition section in the actual case.

A precise statement of the mathematical problem and its solution is given in the next section. Approximations for the cases where the two plates of the transmission line are either far apart or close together are given in the third and fourth sections respectively.

## II. A Precise Formulation

A cross-section of the transmission line we wish to study is shown in figure 1 . The conformal transformation that implicitly determines the fields in the vicinity of the structure shown in Figure 1 is well known. From this transformation, impedance values for the whole structure have beem computed and field plots have been made. ${ }^{1,3}$ In this note we merely wish to show how to divide the plates into sections with equal impedance. This can be done by determining, on the cross-section of one of the plates, the points that divide the plate into sections, each of which carries equal charge per unit length.

By symmetry, there is only one significant division point for the three- and four-section lines. We denote the distance of this point from the center of the plate by $x_{1}$. For the three-section line the other division point is, of course, the same distance on the other side of the center point. For the four-section line there is, in addition to this symmetric division point, a division point at the center itself.

Similarly, for the five- and six-section lines there are only two significant division points, the center of the plate being again a division point of the six-section line.

To determine the proper division points in each case we begin with the appropriate conformal transformation. We denote the stream function by $u$ and, using the coordinate system of figure 1 , set it equal to zero along the $y$ axis above the upper plate. We denote the potential function by $v$ and set it equal to zero along the $x$-axis and equal to $K\left(m_{1}\right)$ on the upper plate, where $K\left(m_{1}\right)$ is the complete elliptic integral of the first kind with modulus $m_{1}$, and $m_{1}$ will be defined later. With this notation we may write the stream function and potential function as implicit functions of $x$ and $y$ in the form ${ }^{1}$

$$
\begin{equation*}
\frac{x}{b}=\frac{2 K(m)}{\pi}\left\{E(u \mid m)-\frac{u E(m)}{K(m)}+\frac{m \operatorname{sn}(u \mid m) \operatorname{cn}(u \mid m) d n(u \mid m) \operatorname{sn}^{2}\left(v^{\prime} \mid m_{1}\right)}{1-\operatorname{dn}^{2}(u \mid m) \operatorname{sn}^{2}\left(v^{\prime} \mid m_{1}\right)}\right\} \tag{1}
\end{equation*}
$$

$$
\begin{align*}
& \frac{y}{b}=\frac{2 K(m)}{\pi}\left\{E\left(v^{\prime} \mid m_{1}\right)-\frac{v^{\prime} E\left(m_{1}\right)}{K\left(m_{1}\right)}+\frac{\pi v}{2 K(m) K\left(m_{1}\right)}\right. \\
&\left.-\frac{d^{2}(u \mid m) \operatorname{sn}\left(v^{\prime} \mid m_{1}\right) \operatorname{cn}\left(v^{\prime} \mid m_{1}\right) \operatorname{dn}\left(v^{\prime} \mid m_{1}\right)}{1-\operatorname{dn}^{2}(u \mid m) \operatorname{sn}^{2}\left(v^{\prime} \mid m_{1}\right)}\right\} \tag{2}
\end{align*}
$$

where

$$
\begin{align*}
& \mathrm{v}^{\prime}=\mathrm{v}+\mathrm{K}\left(\mathrm{~m}_{1}\right)  \tag{3}\\
& \mathrm{m}_{1}=1-\mathrm{m} \tag{4}
\end{align*}
$$

and $m$ is defined by the pair of simultaneous equations

$$
\begin{gather*}
1-m \sin ^{2}\left(\phi_{0}\right)=\frac{E(m)}{K(m)}  \tag{5}\\
\frac{a}{b}=\frac{2}{\pi}\left\{K(m) E\left(\phi_{o} \mid m\right)-E(m) F\left(\phi_{o} \mid m\right)\right\} \tag{6}
\end{gather*}
$$

In equation 6 , $a$ and $b$ are as shown in figure 1 and $\phi_{0}$ is the amplitude of the elliptic integrals. The notation in the above equations is the same as in reference 5 .

To be specific, we will consider only the top plate in the following. On the top plate,

$$
v=k\left(m_{1}\right),
$$

hence

$$
\operatorname{sn}\left(v^{\prime} \mid m_{1}\right)=\operatorname{sn}\left(2 k\left(m_{1}\right) \mid m_{1}\right)=0
$$

and so

$$
\begin{equation*}
x=\frac{2 K(m)}{\pi}\left\{E(u \mid m)-\frac{\mathrm{u} E(\mathrm{~m})}{\mathrm{K}(\mathrm{~m})}\right\} \tag{7}
\end{equation*}
$$

From equation 7, if $x$ is zero, $u$ is either zero or $K(m)$. On the upper side of the plate $u$ is zero at $x=0$ and on the lower side of the plate $u$ is $K(m)$ at $x=0$. The stream function $u$ increases monotonically from zero to $K(m)$ as the point $x$ moves out along the upper side of the plate until it is equal to $a$, and then moves back along the lower side of the plate. From the definition of the stream function, the charge per unit length between any two points on the top plate is given by $\varepsilon_{0}$ times the difference in the values of $u$ at the two points. In particular the charge per unit length on half of the top plate is $\varepsilon_{o} K(m)$. In order to find the point $x_{1}$ such that a fraction $\alpha$ of this charge is situated between $x_{1}$ and the edge of the plate we write the two expressions for $x_{1}$ in terms of $u$ above and below the plate. That is

$$
\begin{align*}
& x_{1}=\frac{2}{\pi}\left\{K(m) E\left(u_{T} \mid m\right)-u_{T} E(m)\right\}  \tag{8}\\
& x_{1}=\frac{2}{\pi}\left\{K(m) E\left(u_{B} \mid m\right)-u_{B} E(m)\right\} \tag{9}
\end{align*}
$$

where

$$
\begin{equation*}
u_{B}-u_{T}=\alpha K(m) \tag{10}
\end{equation*}
$$

Combining these equations:

$$
\begin{equation*}
\mathrm{K}(\mathrm{~m})\left[\mathrm{E}\left(\mathrm{u}_{\mathrm{T}}+\alpha \mathrm{K}(\mathrm{~m}) \mid \mathrm{m}\right)-\mathrm{E}\left(\mathrm{u}_{\mathrm{T}} \mid \mathrm{m}\right)\right]=\alpha \mathrm{K}(\mathrm{~m}) \mathrm{E}(\mathrm{~m}) \tag{11}
\end{equation*}
$$

or using the definition

$$
E(u \mid m)=\int_{0}^{u} \mathrm{dn}^{2}(x \mid m) d x
$$

we may rewrite equation (11) as

$$
\int^{u_{T}+\alpha K(m)} \operatorname{dn}^{2}(x \mid m) d x=\alpha E(m)
$$

For a given $m$ and $\alpha$, equation (12) is a transcendental equation that can be used to determine $u_{T}$. Once $u_{T}$ is known it can be substituted in equation (8) to determine $x_{1}$. This is, in fact, what was done to obtain the data plotted in the continuous curves in figures 3 through 6. For the three-section line $x_{1}$ was determined by setting $\alpha=2 / 3$. For the foursection line $\alpha=1 / 2$. For the five-section line, $\alpha=4 / 5$ determines $x_{1}$ and $\alpha=2 / 5$ determines $x_{2}$. For the six-section line $\alpha=2 / 3$ determines $x_{1}$ while $\alpha=1 / 3$ determines $x_{2}$. In all cases the relation between $m$ and $a / b$ can be determined from equations (5) and (6). When
the numerical calculations were made, actually a pair of equations equivalent to (5) and (6) were used, namely

$$
\begin{equation*}
\mathrm{dn}^{2}\left(u_{0} \mid m\right)=\frac{E(m)}{K(m)} \tag{13}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{a}{b}=\frac{2}{\pi}\left\{K(m) \int_{0}^{u_{o}} \mathrm{dn}^{2}(x \mid m) d x-u_{o} E(m)\right\} \tag{14}
\end{equation*}
$$

III. Plates Far Apart

If the plates are very far apart compared to their width the charge density on each plate arranges itself to be quite close to the charge density that would occur if the plate were isolated in free space. This density is well known to be

$$
\begin{equation*}
\sigma(x)=\frac{Q}{\pi \sqrt{a^{2}-x^{2}}} \tag{15}
\end{equation*}
$$

where $Q$ is the total charge on the plate. To find the values of $X_{i}$ that divide the plate into, say, $N$ sections of equal charge, we simply require that $x_{i}$ satisfies the equation

$$
\begin{align*}
\int_{i}+1 & \sigma(x) d x=\frac{Q}{N} \\
x_{i} &  \tag{16}\\
& =-\frac{N}{2} \rightarrow \frac{N}{2} \quad \text { (N even) } \\
& =\frac{N-1}{2} \quad(N \text { odd })
\end{align*}
$$

This can easily be solved by setting

$$
\begin{equation*}
x=a \sin \theta \tag{17}
\end{equation*}
$$

in equation (16) to obtain

$$
\frac{Q}{\pi} \int_{\theta_{i}}^{\theta_{i}+1} d \theta=\frac{Q}{N} \quad-\pi<\theta_{i}<\pi
$$

or

$$
\begin{equation*}
\theta_{i}+1-\theta_{i}=\frac{\pi}{N} \tag{18}
\end{equation*}
$$

For $N$ even, (17) and (18) may be combined to give the significant division points as the center point, $x_{o}$, and

$$
\begin{equation*}
x_{i}=a \sin \left(\frac{i \pi}{2 N}\right) \quad i=1+\frac{N}{2}-1 \tag{19}
\end{equation*}
$$

For $N$ odd the significant division points are again given by (19), but the range of $i$ is from 1 to (N - I)/2. These values are plotted as the horizontal asymptotes in the upper left portions of the curves in figures 3 through 6.

## IV. Plates Close Together

For the case where the upper plate, of width $2 a$, is several times larger than its height $b$, we assume that the fields near the center $x=0$ are not affected by the fringing caused by the edges at $x= \pm a, i . e .$, the fields at $x=0$ are the same as those that would exist if the upper plate were infinite in extent $(-a \rightarrow-\infty)$. This assumption allows one to extend the left half ( $-a \leq x \leq 0$ ) of the upper plate while keeping the right half ( $0 \leq x \leq a$ ) intact, so that the extended upper plate occupies the region $(-\infty<x \leq a, y=b)$ as shown in figure $2 a$. The charge distribution on the right half of the actual upper plate is assumed to be the same as that on the right half ( $0 \leq \mathrm{x} \leq \mathrm{a}$ ) of the extended upper plate.

It is convenient to use the conformal transformation

$$
\begin{equation*}
\frac{\pi(z-a)}{b}=1+w+\ln w \tag{20}
\end{equation*}
$$

to map the structure depicted in figure $2 a$ from the $z-p$ lane onto the $w$-plane. ${ }^{6}$ Transformed onto the $w-p l a n e$, the structure takes on the simple geometry shown in figure 2 b . By substituting $w=r e^{i \theta}$ into (20) we obtain

$$
\begin{align*}
\frac{\pi(x-a)}{b} & =1+\ln r+r \cos \theta \\
\frac{\pi y}{b} & =\theta+r \sin \theta \tag{21}
\end{align*}
$$

from which corresponding points on the two planes are readily determined; several important points are labeled in figure 2.

Both the upper and lower surfaces of the right half of the upper plate map onto the $w-p l a n e$ as the line segment $A C B$ which has charge only on its
upper surface so that the lines of flux connecting $A C B$ and $A^{\prime} C^{\prime} B^{\prime}$ are semi-circles existing only in the upper half of the w-plane ( $0 \leq \theta \leq \pi$ ). The potential for the simplified geometry in the w-plane can be written down by inspection, viz.

$$
\begin{equation*}
\phi=\frac{\left(\phi_{2}-\phi_{1}\right)}{\pi} \theta+\phi_{1} \quad(0 \leq \theta \leq \pi) \tag{22}
\end{equation*}
$$

The charge on the strip $A C B$, by Gauss's law, is

$$
\begin{equation*}
q_{A B}=\varepsilon_{0} \int_{r_{A}}^{r_{B}} \nabla \phi \cdot \underline{u}_{\theta} d r \tag{23}
\end{equation*}
$$

which gives

$$
q_{A B}=\varepsilon_{0} \ln \left(r_{B} / r_{A}\right)
$$

It is assumed that the total charge on the actual upper plate, of width 2 a , is $q_{t}=2 q_{A B}$. Setting $\theta=\pi$ in (21) and evaluating the result at $x=0$, we see that the radii $r_{A}$ and $r_{B}$ satisfy

$$
\begin{array}{ll}
-\frac{\pi a}{b}=1+\ln r_{A}-r_{A} & \left(r_{a}<1\right)  \tag{24}\\
-\frac{\pi a}{b}=1+\ln r_{B}-r_{B} & \left(r_{B}>1\right)
\end{array}
$$

We want to divide the upper plate into $\mathbb{N}$ sections such that the charge
$q_{N}$ on each section is the same, viz., $q_{N}=q_{t} / N$. Clearly, for the simple case of $N=2$, dividing the upper plate at $x=0$ into two halves gives two sections with the same amount of charge. Since the charge on the upper plate is not uniformly distributed but is instead peaked toward the edges, the problem in general is more difficult. In general we want to determine a position $X_{i}$ such that the charge on the section of the upper plate ( $x_{i} \leq x \leq a$ ) to the right of $x_{i}$ is $\alpha q_{t} / 2$ while the charge to the left $\left(-a \leq x \leq x_{i}\right)$ is $q_{t}(1-\alpha / 2)$. By proper choice of $\alpha$ we can divide the upper plate into as many equally charged sections as we want.

Corresponding to a particular value of $\alpha$, the radii $r_{G}$ and $r_{H}$ in the $w$-plane satisfy

$$
\begin{equation*}
\ln \left(r_{H} / r_{G}\right)=c_{\alpha} \tag{25}
\end{equation*}
$$

where $c_{\alpha}=\alpha \ln \left(r_{B} / r_{A}\right)$, the radii $r_{A}$ and $r_{B}$ being obtained from (24) for each geometry. Using (24) we may write, for the sake of convenience, $\ln \left(r_{B} / r_{A}\right)=r_{B}-r_{A}$ so that $c_{\alpha}=\alpha\left(r_{B}-r_{A}\right)$.

In addition to (25), which can be written as

$$
\begin{equation*}
r_{H}=r_{G} e^{c_{\alpha}} \tag{26}
\end{equation*}
$$

the radii $\quad r_{G}$ and $r_{H}$ satisfy

$$
\begin{array}{ll}
\frac{\pi\left(x_{i}-a\right)}{b}=1+\ln r_{G}-r_{G} & \left(r_{G}<1\right) \\
\frac{\pi\left(x_{i}-a\right)}{b}=1+\ln r_{H}-r_{H} & \left(r_{H}>1\right) \tag{27b}
\end{array}
$$

From (27) we obtain $\ln \left(r_{H} / r_{G}\right)=r_{H}-r_{G}$ in which (26) may be substituted to eliminate $r_{H}$, giving

$$
\begin{equation*}
r_{G}=\frac{c_{\alpha}}{e^{c_{\alpha}}-1} \leq 1 \tag{28}
\end{equation*}
$$

For a particular value of $c_{\alpha}$ we use (28) to compute $r_{G}$ which, in turn, is used to compute $X_{i}$ according to (27a)

$$
\begin{equation*}
\frac{x_{i}}{b}=\frac{a}{b}-\frac{1}{\pi}\left(r_{G}-1-\ln r_{G}\right) \tag{29}
\end{equation*}
$$

alternatively

$$
\begin{equation*}
\frac{x_{i}}{b}=\frac{a}{b}-\frac{1}{\pi}\left(r_{H}-1-\ln r_{H}\right) \tag{30}
\end{equation*}
$$

where

$$
\begin{equation*}
r_{H}=\frac{c_{\alpha}}{1-e^{-c_{\alpha}}} \geq 1 \tag{31}
\end{equation*}
$$

For geometries with $a / b>10$ a good approximation for $x_{i}$ is

$$
\begin{equation*}
\frac{x_{i}}{b} \approx \frac{a}{b}-\frac{1}{\pi}\left(\gamma_{i}-1-\ln \gamma_{i}\right) \tag{32}
\end{equation*}
$$

where

$$
\begin{equation*}
\gamma_{i}=\alpha(1+\pi a / b) \tag{33}
\end{equation*}
$$

This approximation assumes that both $r_{A}$ and $\ln r_{B}$ are negligible compared to $r_{B}$ and that $e^{-C_{\alpha}}$ is negligible compared to unity.

Equation (29) is plotted in figures 3 through 6 as the curves starting at the point $a / b=1$. For $a / b>10$ these curves are indistinguishable from those obtained from the approximate formula (32) and also indistinguishable from their actual values. The horizontal asymptotes at the lower right portions of the curves in figures 3 through 6 are plots of the crude approximation

$$
\begin{equation*}
\frac{x_{i}}{b}=\frac{a}{b}(1-\alpha) \tag{34}
\end{equation*}
$$

which is equivalent to dividing the plate into $N$ equal sections.

In table 1 of this appendix we present again, in a form from which more accurate data can be obtained, the information used to produce figures 3 through 6 of note 85.

For divisions of the two-plate line other than those of table 1 , tables 2, 3 and 4 may be useful. The latter tables give the positions of the points (tabulated, as in table l, as a fraction of the half-width of the plates) that contain a fraction $\alpha$ of the admittance of a half-plate between the tabulated point and the outside edge of the plate.

The numbers presented here are accurate to within $\pm .0003$. Linear interpolation between the entries in tables 2, 3 and 4 will give 3-figure accuracy except for the lowest pair of $\alpha^{\prime}$ s.
